Class(12th)

Introduction to Vector
Algebra

1. **Vector** - A vector is a quantity having both magnitude and direction, such as displacement, velocity, force and acceleration. AB is a directed line segment. It is a vector AB and its direction is from A to B. $\overrightarrow{A} \quad \quad \quad \overrightarrow{B}$

Initial Points - The point A where from the vector AB starts is known as initial point. **Terminal Point** - The point B, where it ends is said to be the terminal point.

Magnitude - The distance between initial point and terminal point of a vector is the magnitude or length of the vector AB. It is denoted by $|\overrightarrow{AB}|$ or AB.

2. **Position Vector** - Consider a point p (x, y, z) in space. The vector OP with initial point, origin O and terminal point R is called

the position vector of P.

3. **Types of Vectors**

- (i) **Zero Vector Or Null Vector** - A vector whose initial and terminal points coincide is known as zero vector ($\vec{0}$).
- (ii) **Unit Vector** - A vector whose magnitude is unity is said to be unit vector. It is denoted as \hat{a} so that $|\hat{a}| = 1$.
- (iii) **Co-initial Vectors** - Two or more vectors having the same initial point are called co-initial vectors.
- (iv) **Collinear Vectors** - If two or more vectors are parallel to the same line, such vectors are known as collinear vectors.
- (v) **Equal Vectors** - If two vectors a and b have the same magnitude and direction regardless of the positions of their initial points, such vectors are said to be equal *i.e.*, $a = b$.
- (vi) **Negative of a vector** - A vector whose magnitude is same as that of a given vector AB, but the direction is opposite to that of it, is known as negative of vector AB *i.e.*, $\vec{BA} = -\vec{AB}$

4. **Sum of Vectors**

- (i) **Sum of vectors a and b** let the vectors a and b be so positioned that initial point of one coincides with terminal point of the other. If $a = \vec{AB}$, $b = \vec{BC}$. Then the vector $a + b$ is represented by the third side of $\triangle ABC$. *i.e.*, $\vec{AB} + \vec{BC} = \vec{AC}$... (i)

$$AB + BC = -CA$$

$$AB + BC + CA = 0$$

This is known as the triangle law of vector addition. Further $AC = -CA$

when sides of a triangle ABC are taken in order i.e. initial and terminal points coincide. Then $AB + BC + CA = 0$

(ii) **Parallelogram law of vector addition** - If the two vectors a and b are represented by the two adjacent sides OA and OB of a parallelogram OACB, then their sum $a + b$ is represented in magnitude and direction by the diagonal OC of

parallelogram through their common point O i.e., $OA + OB = OC$

5. Multiplication of Vector by a Scalar- Let a be the given vector and λ be a scalar, then product of λ and $a = \lambda a$

(i) when λ is +ve, then a and λa are in the same direction.

(ii) when λ is -ve, then a and λa are in the opposite direction. Also $|\lambda a| = |\lambda| |a|$.

6. Components of Vector - Let us take the points A (1,0,0), B (0,1,0) and C (0,0,1) on the coordinate axes OX, OY and OZ respectively. Now, $|OA| = 1$, $|OB| = 1$ and $|OC| = 1$. Vectors OA, OB and OC each having magnitude 1 is known as unit vector. These are denoted by \hat{i} , \hat{j} and \hat{k} .

Consider the vector OP, where P is the point (x, y, z). Now OQ, OR, OS are the projections of OP on coordinate axes.

$$OQ = x, OR = y, OS = z$$

$$\vec{OP} = x\hat{i} + y\hat{j} + z\hat{k} \quad , \quad |\vec{OP}| = \sqrt{x^2 + y^2 + z^2} = |\vec{r}|$$

x, y, z are called the scalar components and $x\hat{i}, y\hat{j}, z\hat{k}$ are called the vector components of vector OP . **Vector**

7. **joining two points** - Let $P(x_1, y_1, z_1)$ and $P_2(x_2, y_2, z_2)$ be the two points. Then vector joining the

points P_1 and P_2 . Join P_1, P_2 with O . Now $\vec{OP_2} = \vec{OP_1} + \vec{P_1P_2}$ (by triangle law)

$$\therefore \vec{P_1P_2} = \vec{OP_2} - \vec{OP_1}$$

$$= (x_2\hat{i} + y_2\hat{j} + z_2\hat{k}) - (x_1\hat{i} + y_1\hat{j} + z_1\hat{k}) = (x_2 - x_1)\hat{i} + (y_2 - y_1)\hat{j} + (z_2 - z_1)\hat{k} \quad |\vec{P_1P_2}| = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2} \quad \text{Section}$$

Formula

PR

- (i) A line segment PQ is divided by a point R in the ratio $m:n$ internally i.e.,
If \vec{a} and \vec{b} are the position vectors of P and Q then the position vector \vec{r} of R is given by - $\frac{m\vec{b} + n\vec{a}}{m+n}$

$$m+n$$

$P(?)$

(K)

If R be the mid-point of PQ , then $\vec{r} = \frac{\vec{a} + \vec{b}}{2}$

- (ii) when R divides PQ externally, i.e., $|a| > |b|$ n

Then $r = \frac{mb-na}{c^2}$

9. Projection of vector along a directed line - Let the vector AB makes an angle θ with directed line f .

Projection of AB on $f = |AB| \cos \theta = AC = p$.

The vector \vec{p} is called the projection vector. Its magnitude is p , which is known as projection of vector

$\cos \theta =$

Now projection $AC = |AB| \cos \theta =$

$\frac{\vec{AB} \cdot \vec{AC}}{|\vec{AC}|}$

$|\vec{AC}|$

$$= \vec{AB} \cdot \left(\frac{\vec{AC}}{|\vec{AC}|} \right), \text{ If } \vec{AB} = \vec{a}, \text{ then } \vec{AC} = \frac{\vec{p}}{|\vec{p}|}$$

$$\vec{b} = \vec{a} \cdot \left(\frac{\vec{b}}{|\vec{b}|} \right) = \vec{a} \cdot \hat{b}$$

AB. The angle θ between AB and AC is given by

10. Scalar Product of Two Vectors (Dot Product) - Scalar Product of two vectors \vec{a} and \vec{b} is defined as

$$\vec{a} \cdot \vec{b} = |\vec{a}| |\vec{b}| \cos \theta \quad |\vec{AB}| |\vec{AC}|$$

Where θ is the angle between \vec{a} and \vec{b} ($0 < \theta < \pi$)

(i) when $\theta = 0$, then $\vec{a} \cdot \vec{b} = |\vec{a}| |\vec{b}| = ab$ Also $\vec{a} \cdot \vec{a} = |\vec{a}| |\vec{a}| = a \cdot a = a^2$

$$\vec{i} \cdot \vec{i} = \vec{j} \cdot \vec{j} = \vec{k} \cdot \vec{k} = 1$$

Thus, the projection of \vec{a} on

(ii) when $\theta = \frac{\pi}{2}$, then $\vec{a} \cdot \vec{b} = |\vec{a}| |\vec{b}| \cos \frac{\pi}{2} = 0$ $\vec{i} \cdot \vec{j} = \vec{j} \cdot \vec{k} = \vec{k} \cdot \vec{i} = 0$

11. Vector Product of two Vectors (Cross Product) - The vector product of two non-zero vectors \vec{a} and \vec{b} , denoted by $\vec{a} \times \vec{b}$ is defined as

$\vec{a} \times \vec{b} = |\vec{a}| |\vec{b}| \sin \theta \vec{n}$, where θ is the angle between \vec{a} and \vec{b} , $0 < \theta < \pi$. Unit vector \vec{n} is perpendicular to both vectors \vec{a} and \vec{b} such that $\vec{a} \cdot \vec{b}$ and \vec{n} form a right handed orthogonal system.

(i) If $\theta = 0$, then $\vec{a} \times \vec{b} = 0$, $\therefore \vec{a} \times \vec{a} = 0$ and $\vec{i} \times \vec{j} = \vec{j} \times \vec{k} = \vec{k} \times \vec{i} = 0$

(ii) If $\theta = \frac{\pi}{2}$ then $\vec{a} \times \vec{b} = |\vec{a}| |\vec{b}| \vec{n}$ $\vec{i} \times \vec{j} = \vec{j} \times \vec{k} = \vec{i}$, $\vec{k} \times \vec{i} = \vec{j}$

Also, $\vec{j} \times \vec{i} = -\vec{k}$, $\vec{k} \times \vec{j} = -\vec{i}$ and $\vec{i} \times \vec{k} = -\vec{j}$

$$|\vec{a} \times \vec{b}| = |\vec{a}| |\vec{b}| \sin \theta$$

1. Direction Cosines - Let OX, OY, OZ be the positive coordinate axes, P(x, y, z) be any point in the space. Let OP makes angles α, β, γ with coordinate axes OX, OY, OZ. The angles α, β, γ are known as direction

angles, cosine of these angles i.e.,

$\cos \alpha, \cos \beta, \cos \gamma$ are called direction cosines of line OP. these direction cosines are denoted by, l, m, n

i.e., $l = \cos \alpha, m = \cos \beta, n = \cos \gamma$

2. Relation Between l, m, n and Direction Ratios -

The perpendiculars PA, PB, PC are drawn on coordinate axes OX, OY, OZ respectively. Let $|OP| = r$

In $\triangle OAP$, $\angle A = 90^\circ, \cos \alpha =$

$\frac{x}{r}$. In $\triangle OBP$, $\angle B = 90^\circ, \cos \beta = \frac{y}{r}$ $\therefore x = lr, y = mr$

In $\triangle OCP$, $\angle C = 90^\circ, \cos \gamma = \frac{z}{r} = n$,

$\therefore z = nr$

Thus the coordinates of P may be expressed as (lr, mr, nr) Also $OP^2 = x^2 + y^2 + z^2 = (lr)^2 + (mr)^2 + (nr)^2 \Rightarrow l^2 + m^2 + n^2 = 1$

Set of any three numbers, which are proportional to direction cosines are called direction ratio of the vector. Direction ratio are denoted by a, b and c .

The numbers l, m and n , proportional to the direction cosines, hence, they are also direction ratios of vector OP.

3. Properties of Vector Addition -

1. For two vectors a, b the sum is commutative i.e., $a + b = b + a$

2. For three vectors a, b and c , the sum of vectors is associative i.e., $(a + b) + c = a + (b + c)$

4. Additive Inverse of Vector a - If there exists vector $-a$ such that $a + (-a) = -a + a = 0$ then $-a$ is called the additive inverse of a

5. Some Properties - Let $a = a_1 i + a_2 j + a_3 k$ and $b = b_1 i + b_2 j + b_3 k$

(i) $a + b = (a_1 i + a_2 j + a_3 k) + (b_1 i + b_2 j + b_3 k) = (a_1 + b_1) i + (a_2 + b_2) j + (a_3 + b_3) k$

(ii) $a = b$ or $(a_1 i + a_2 j + a_3 k) = (b_1 i + b_2 j + b_3 k) \Rightarrow a_1 = b_1, a_2 = b_2, a_3 = b_3$

(iii) $Xa = X(a_1 i + a_2 j + a_3 k) = (Xa_1) i + (Xa_2) j + (Xa_3) k$

(iv) a and b are parallel, if and only if there exists a non zero scalar X such that $b = Xa$

$$i.e. b_j i + b_2 j + b_3 k = X(a_j i + a_2 j + a_3 k) = (Xa_1)i + (Xa_2)j + (Xa_3)k \dots b_j = la_p, b_2 = Xa_2, b_3 = Xa_3 / . \quad =$$

$$= \quad = X$$

6. Properties of scalar product of two vectors (Dot Product)

$$(i) \quad \cos \theta = \frac{a \cdot b}{|a||b|}$$

$$\text{If } a = a_1 i + a_2 j + a_3 k \text{ and } b = b_1 i + b_2 j + b_3 k \text{ Then, } a \cdot b = (a_1 i + a_2 j + a_3 k) \cdot (b_1 i + b_2 j + b_3 k) \\ a \cdot b = a_1 b_1 + a_2 b_2 + a_3 b_3$$

$$|a| = \sqrt{a_1^2 + a_2^2 + a_3^2}, |b| = \sqrt{b_1^2 + b_2^2 + b_3^2}$$

$$\therefore \cos \theta = \frac{a \cdot b}{|a||b|} = \frac{a_1 b_1 + a_2 b_2 + a_3 b_3}{\sqrt{a_1^2 + a_2^2 + a_3^2} \cdot \sqrt{b_1^2 + b_2^2 + b_3^2}}$$

$$(ii) \quad \text{is commutative i.e., } a \cdot b = b \cdot a$$

$$(iii) \quad \text{If } a \text{ is a scalar, then } (a a) \cdot b = a(a \cdot b) = a(a b)$$

7. Properties of Vector Product of two Vectors (Cross Product)-

$$(i) \quad (a) \text{ If } a = 0 \text{ or } b = 0, \text{ then } a \times b = 0$$

$$(b) \text{ If } a \parallel b, \text{ then } a \times b = 0$$

$$(ii) \quad a \times b \text{ is not commutative}$$

$$\text{i.e. } a \times b = b \times a, \text{ but } a \times b = -b \times a$$

$$(iii) \quad \text{If } a \text{ and } b \text{ represent adjacent sides of a parallelogram, then its area } |a \times b|$$

$$(iv) \quad \text{If } a, b \text{ represent the adjacent sides of a triangle, then its area} = \frac{1}{2} |a \times b|$$

$$(v) \quad \text{Distributive property } a \times (b + c) = a \times b + a \times c$$

$$(a) \quad \text{If } a \text{ be a scalar, then } a(a \times b) = (a a) \times b = a \times (a b)$$

$$(b) \quad \text{If } a = a_1 i + a_2 j + a_3 k, \text{ and } b = b_1 i + b_2 j + b_3 k$$

$$j \quad k$$

$$\text{Then, } a \times b = \begin{vmatrix} i & j & k \\ a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \end{vmatrix}$$

$$a_2 a_3$$

$$b_2 b_3$$

$$8. \text{ If } \alpha, \beta, \gamma \text{ are the direction angles of the vector } a = (a_1 i + a_2 j + a_3 k) \cdot \text{ Then direction cosines of } a \text{ are given as}$$

$$\cos \alpha = \frac{a_1}{|a|}, \cos \beta = \frac{a_2}{|a|}, \cos \gamma = \frac{a_3}{|a|}$$

9. Scalar Product of Two Vectors (Dot Product) - Scalar Product of two vectors \mathbf{a} and \mathbf{b} is defined as

where θ is the angle between \mathbf{a} and \mathbf{b}

(i) When $\theta = 0$, then $\mathbf{a} \cdot \mathbf{b} = |\mathbf{a}| |\mathbf{b}|$. Also $\mathbf{a} \cdot \mathbf{a} = |\mathbf{a}|^2$, $\mathbf{i} \cdot \mathbf{i} = \mathbf{j} \cdot \mathbf{j} = \mathbf{k} \cdot \mathbf{k} = 1$

(ii) When $\theta = \pi$, $\mathbf{a} \cdot \mathbf{b} = -|\mathbf{a}| |\mathbf{b}|$
